Reg. no:192472273

Code: DSA0307

Course: Natural Language Processing

Experiment 2: Finite State Automaton (String Ending with 'ab')

Aim:

To implement a basic Finite State Automaton (FSA) that recognizes strings ending with "ab" using Python.

Algorithm:

1. Read the input string.
2. Check whether the string ends with "ab".
3. If it ends with "ab", accept the string.
4. Otherwise, reject the string.
5. Display the result.

Python Code:

```
string = input("Enter a string: ")
```

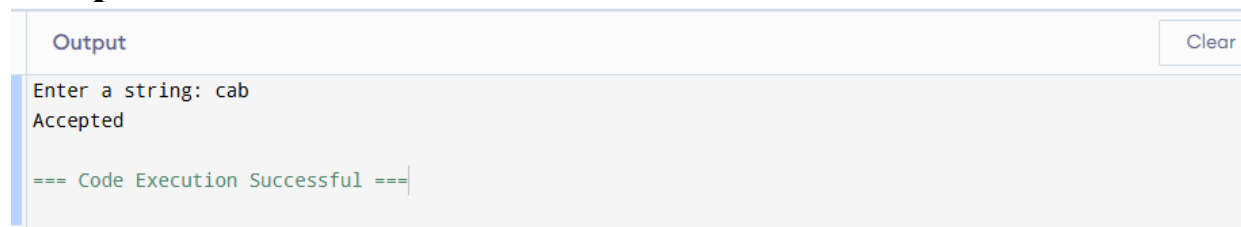

```
if string.endswith("ab"):
```

```
    print("Accepted")
```

```
else:
```

```
    print("Rejected")
```

Output:

The screenshot shows a code editor with the following Python code:

```
string = input("Enter a string: ")

if string.endswith("ab"):
    print("Accepted")
else:
    print("Rejected")
```

The output of the code is displayed in a box labeled "Output". It shows the input "cab" and the output "Accepted". Below the output, it says "=== Code Execution Successful ===".

Result:

The program successfully recognized whether the given string ends with "ab".
